## **Asymmetric Proof Of Work**

Developed by Alex Biryukov and Dmitry Khovratovich at the University of Luxembourg, the Equihash algorithm is an asymmetric memory-orientated proof-of-work system that is based on the generalized birthday problem. Equihash is memory-orientated in that it is ‘memory-hard’, meaning that the amount of proof-of-work mining that can be done is predominantly determined by how much memory i.e. RAM that one possesses.

Based On The University of Luxembourg's Interdisciplinary Centre for Security, Reliability and Trust at the 2016 Network and Distributed System Security Symposium. The algorithm is based on a generalization of the Birthday problem which finds colliding hash values. It has severe time-space trade-offs but concedes vulnerability to unforeseen parallel optimizations. It was designed such that parallel implementations are bottle-necked by memory

## **Equihash - Wikipedia**

Equihash is a tunable asymmetric proof of work algorithm where it is difficult to generate a proof, but easy to verify one. The algorithm makes it difficult to build custom hardware to generate the proof by ensuring forced CPU and memory trade offs.

Equihash is the proof-of-work hash function in the Zcash and Bitcoin Gold blockchains. It is memory-intensive hash-function (requires a lot of RAM for fast calculation), so it is believed to be ASIC-resistant. How does Equihash work? Uses BLAKE2b to compute 50 MB hash dataset from the previous blocks in the blockchain (until the current block).

What Constitutes a good Proof of Work?

Some criteria for a good Proof of Work system in a decentralized blockchain with fair distribution of newly mined coins have been formalized by Biryukov and Khovratovich in their Equihash paper:

**Asymmetry:** The Proof of Work needs to be hard to produce, but easy to verify.

Hashing is an example of an asymmetric task.
